Body Mass Index

Joseph P. Iser
BMI is a person's weight in kilograms divided by the square of height in meters.

BMI does not measure body fat directly, but research has shown that BMI is moderately correlated with more direct measures of body fat\textsuperscript{1,2,3}.

BMI appears to be as strongly correlated with various metabolic and disease outcome as are these more direct measures of body fatness\textsuperscript{4,5,6,7,8,9}.

In general, BMI is an inexpensive and easy-to-perform method of screening for weight category, for example underweight, normal or healthy weight, overweight, and obesity.
How is BMI used?

- A high BMI can be an indicator of high body fatness. BMI can be used as a screening tool but is not diagnostic of the body fatness or health of an individual.

- To determine if a high BMI is a health risk for individuals, a healthcare provider would need to perform further assessments. These assessments might include skinfold thickness measurements, evaluations of diet, physical activity, family history, and other appropriate health screenings.
What are the BMI trends for adults in the United States?

- The prevalence of adult BMI greater than or equal to 30 kg/m² (obese status) has greatly increased since the 1970s. Recently, however, this trend has leveled off, except for older women. Obesity has continued to increase in adult women who are age 60 years and older.

- To learn more about the trends of adult obesity, visit Adult Obesity Facts (http://www.cdc.gov/obesity/data/adult.html).
BMI can be used for population assessment of overweight and obesity. Because calculation requires only height and weight, it is inexpensive and easy to use for clinicians and for the general public.

BMI can be used as a screening tool for body fatness but is not diagnostic.
What are some other ways to assess excess body fatness besides BMI?

- Other methods to measure body fatness include skinfold thickness measurements (with calipers), underwater weighing, bioelectrical impedance, dual-energy x-ray absorptiometry (DXA), and isotope dilution.$^1,^2,^3$.
- However, these methods are not always readily available, and they are either expensive or need to be conducted by highly trained personnel.
- Many of these methods can be difficult to standardize across observers or machines, complicating comparisons across studies and time periods.
BMI is calculated the same way for both adults and children. The calculation is based on the following formula using US measurements:

- Formula: weight (lb)/[height (in)]² x 703
- Calculate BMI by dividing weight in pounds (lbs) by height in inches (in) squared and multiplying by a conversion factor of 703.
- Example: Weight = 150 lbs, Height = 5'5" (65"")
  Calculation: \[150 ÷ (65)^2\] x 703 = 24.96
How is BMI interpreted for adults?

<table>
<thead>
<tr>
<th>BMI</th>
<th>Weight Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Below 18.5</td>
<td>Underweight</td>
</tr>
<tr>
<td>18.5 – 24.9</td>
<td>Normal or Healthy Weight</td>
</tr>
<tr>
<td>25.0 – 29.9</td>
<td>Overweight</td>
</tr>
<tr>
<td>30.0 and Above</td>
<td>Obese</td>
</tr>
</tbody>
</table>
BMI is interpreted differently for children and teens, even though it is calculated using the same formula as adult BMI. BMI needs to be age and sex-specific because the amount of body fat changes with age, and the amount of body fat differs between girls and boys. The CDC BMI-for-age growth charts take into account these differences and visually show BMI as a percentile ranking. These percentiles were determined using representative data of the U.S. population of 2-to 19-year-olds that were collected in various surveys from 1963–65 to 1988–94.
Obesity among 2- to 19-year-olds is defined as a BMI at or above the 95th percentile of children of the same age and sex in this 1963 to 1994 reference population.

For example, a 10-year-old boy of average height (56 inches) who weighs 102 pounds would have a BMI of 22.9. This would place the boy in the 95th percentile for BMI – meaning that his BMI is greater than that of 95% of similarly aged boys in this reference population – and he would be considered to have obesity.

For more information and to access the [CDC Growth Charts](http://www.cdc.gov/growthcharts/clinical_charts.htm)

For adults, the interpretation of BMI does not depend on sex or age. Read more about interpreting adult BMI[http://www.cdc.gov/healthyweight/assessing/bmi/adult_bmi/index.html#InterpretedAdults].
How good is BMI as an indicator of body fatness?

- The correlation between the BMI and body fatness is fairly strong\textsuperscript{1,2,3,7}, but even if 2 people have the same BMI, their level of body fatness could easily differ\textsuperscript{12}.

- In general,
  - At the same BMI, women tend to have more body fat than men.
  - At the same BMI, Blacks have less body fat than do Whites\textsuperscript{13,14}, and Asians have more body fat than do Whites\textsuperscript{15}.
  - At the same BMI, older people, on average, tend to have more body fat than younger adults.
  - At the same BMI, athletes have less body fat than do non-athletes.
Accuracy

- The accuracy of BMI as an indicator of body fatness also appears to be higher in persons with higher levels of BMI and body fatness\(^{16}\).
- While a person with a very high BMI (e.g., 35 kg/m\(^2\)) is very likely to have high body fat, a relatively high BMI can be the result of either high body fat or high lean body mass (muscle and bone).
- A healthcare provider should perform appropriate health assessments in order to evaluate an individual's health status and risks.
People who are obese are at increased risk for many diseases and health conditions, including the following: 10, 17, 18

- All-causes of death (mortality)
- High blood pressure (Hypertension)
- High LDL cholesterol, low HDL cholesterol, or high levels of triglycerides (Dyslipidemia)
- Type 2 diabetes
- Coronary heart disease
- Stroke
What are the health consequences of obesity for adults?

- People who are obese are at increased risk for many diseases and health conditions, including the following: 10, 17, 18
  - Gallbladder disease
  - Osteoarthritis (a breakdown of cartilage and bone within a joint)
  - Sleep apnea and breathing problems
  - Chronic inflammation and increased oxidative stress19,20
  - Some cancers (endometrial, breast, colon, kidney, gallbladder, and liver)
  - Low quality of life
  - Mental illness such as clinical depression, anxiety, and other mental disorders21,22
