For the week ending November 21, 2009:

- Influenza activity persists throughout Southern Nevada, although it has continued to decrease over the first three weeks of November.
- Several surveillance systems are continuing to show a decrease in influenza activity. However, it is not possible to determine if this is a short-term aberration or the beginning of a trend of decreasing influenza activity.
- There is currently no evidence of increased severity of disease in Southern Nevada. Posting of the nation-wide report has been delayed until November 30 due to Thanksgiving holiday.
- Local laboratory surveillance indicates that nearly all reported cases of influenza are the result of 2009 Influenza A (H1N1).
- 232 cases, including 15 hospitalizations and 3 deaths were reported to the health district. The deaths include a 25-year-old female with no underlying health conditions, a 59-year-old female with underlying health conditions, and a 49-year-old female with underlying health conditions who was visiting from another country.

**Summary**

**Severity**

There is currently no evidence of increased severity of disease in Southern Nevada or in the United States. An indicator of the severity of disease, the proportion of hospitalized patients in Clark County requiring intensive care unit admission, has continued to decline over the past three weeks. During September and early October, about one-third of hospitalized patients were admitted to the intensive care unit; for the first half of November, one-quarter of hospitalized patients required admission to the intensive care unit; in the past week there were no admissions to ICU. Three influenza-related deaths were reported last week, and two of the three deaths occurred in persons who were at higher risk for serious disease as a result of underlying health conditions (Figure 3.5).

**Circulating Strains**

Local and national laboratory surveillance indicates that nearly all reported cases of influenza are the result of 2009 Influenza A (H1N1). Local pediatric laboratory surveillance has identified no seasonal influenza A H1 or H3 infections and only one influenza B infection out of 278 samples tested since the beginning of influenza season (Figure 1.1 and Table 1.1). This is consistent with national surveillance (Figure 1.2 and Table 1.2).

**Current Status**

Circulation

Over the first three weeks of November, influenza activity decreased in Southern Nevada. US statistics for the third week in November will be posted November 30, due to Thanksgiving holiday. Nationally, for the second week of November, all ten geographic regions of the country continued to report elevated levels of influenza, and 43 states reported widespread geographic distribution of influenza, down from 44 states in the previous week (Source: CDC FluView). Local laboratory testing is showing a decrease in the testing positivity rates (Figure 1.1 and Table 1.1). Sentinel provider reports of patients seeking care for influenza-like illness has displayed the same trend (Figure 2.1). The number of patients hospitalized for influenza decreased during the third week of November (Figure 3.4 and Table 3.1).

**Antiviral Resistance**

The circulating strain of 2009 Influenza A (H1N1) continues to display sensitivity to oseltamivir and zanamivir and resistance to adamantanes. Although sporadic cases of oseltamivir-resistance have been identified in the United States, nearly all patients had documented treatment or prophylaxis with oseltamivir, and occasional development of oseltamivir resistance during treatment or prophylaxis is not unexpected. Since April of 2009, a total of 21 cases of oseltamivir-resistance have been identified in the United States. Twelve of these patients had documented exposure to oseltamivir through either treatment or chemoprophylaxis, one patient had no documented oseltamivir exposure, and one patient is under investigation to determine exposure to oseltamivir. Southern Nevada Influenza Update Number 6: November 25, 2009

Section One: Laboratory Surveillance

Enhanced pediatric influenza surveillance (EPIS) is conducted through four Clark County, NV medical practices. Each practice submits up to 10 specimens each week from pediatric patients presenting with respiratory disease and the specimens are tested for influenza and typed by RT-PCR. National surveillance is conducted through laboratories participating in the Center for Disease Control and Prevention (CDC) National Respiratory and Enteric Virus Surveillance System (NREVSS) program.

Note: National data lags local data by one week, thus national data for the most recent week are unavailable. Source: CDC/NREVSS
Section Two: Sentinel Physician Influenza-Like Illness Surveillance

Data from physicians enrolled in the Center for Disease Control and Prevention’s Outpatient Influenza-like Illness Surveillance Network (ILINet) indicate the percentage of all patients in a given week presenting with influenza-like illness (ILI), which is defined as a fever and either a cough or sore throat.

Figure 2.1 Percentage of Visits for Influenza-Like Illness Reported to ILINet, Locally and Nationally

Note: ILI data collection for the previous week is not complete when this report is generated, and results will lag other parts of this report by one week. Source: CDC/ILINet

Section Three: Clark County Reportable Disease Surveillance

Per Nevada Administrative Code 441A.575, healthcare providers and laboratories must report all laboratory-confirmed cases of influenza to the health authority. Reported hospitalizations are further investigated for the presence of underlying risk factors and for the severity of illness, including intensive care unit (ICU) admission.

Textbox 3.1 Details of Influenza-Related Deaths, Clark County, Week Ending November 21, 2009

3 deaths:
- 25F without underlying conditions
- 49F with underlying conditions
- 59F with underlying conditions

Source: Southern Nevada Health District
Note: Case and hospitalization data for the most recent week are limited to those cases reported in the one-week period ending on the date listed, and are based solely on the date in which the case was reported to SNHD. Cases listed as “Novel H1N1 Influenza” are confirmed by RT-PCR. Cases listed as “Influenza” include all patients who tested positive by a rapid influenza test and have either had no confirmatory testing or confirmatory testing indicating the presence of seasonal influenza. Case categories are mutually exclusive, as are hospitalization categories. Deaths listed are by the date on which the patient died. Cumulative totals may not add up to the current week total plus the cumulative total from the previous week, as cases from previous weeks can be reclassified from Influenza to Novel H1N1 based on new lab results, and duplicates are identified and removed.
